

SEED ROUND · INVESTOR PRESENTATION

The **deepest** liquidity layer on Solana.

A fully on-chain central limit order book with virtualized depth across native, intent, and aggregated liquidity.

3

Liquidity layers,
one unified book

AVL

Aggregated fallback,
subject to user limits

Day 1

Deep books on
every listed pair

VIRTUALIZED DEPTH

Order books run global markets. On-chain, they launch empty.

\$1.6T

Solana DEX spot volume in 2025,
second only to Binance

\$100T+

Annual CLOB volume across equities,
FX, and crypto exchanges

0

Solana CLOBs with unified
external liquidity depth

THE CLOB PARADOX

Central limit order books are the dominant market structure in every mature asset class, from NYSE and Nasdaq to Binance and Bybit. Serious traders demand visible depth, native limit orders, and precise execution. On-chain, the model collapses at launch: an empty book attracts no takers, no takers means no makers, and the venue dies before it ever prices a trade.

SOLANA'S MISSING PIECE

Manifest, Phoenix, and OpenBook validate demand for native on-chain order books. But each venue is limited to liquidity posted directly into its own book. AMMs hold most Solana liquidity, and traders still cannot see that liquidity as executable book depth. The volume is here; liquidity remains fragmented.

Book launches empty

Takers stay away

Makers never arrive

Three liquidity sources. One unified book.

1

Real Limit and Market Orders

User orders are escrowed on-chain in UserVault PDAs: hard commitment, trustless cancellation, and zero counterparty discretion. Full support for professional order types including Limit, IOC, FOK, and Post-Only.

PRIORITY

2

Intent Orders

Market makers post signed intent directly to the book. Liquidity is supplied just in time at settlement, so one maker-controlled wallet or vault balance can support quotes across multiple markets without being locked to each order. Access is gated by on-chain reputation.

DEEP LIQUIDITY

3

AVL: Aggregated Virtualized Liquidity

Strata samples live liquidity across Sonar routes and AMM pools, then virtualizes it as executable depth on the book. It is not cosmetic. Takers trade directly against it, and every pair is deep from day one.

ROUTE FALLBACK

Every taker order cascades through the stack in strict priority. AVL backstops the book with reachable external liquidity, subject to user limits and live route availability.

AVL: Aggregated Virtualized Liquidity

Strata samples real liquidity through Sonar and on-chain AMMs, then virtualizes it as executable depth on the order book. It is not a UI overlay or a projection. Takers trade directly against this depth with atomic execution through CPI.

Deep on Day One

Any SPL pair with on-chain liquidity is deep from the moment it lists. No market makers to recruit, no bootstrapping period, and no paid incentive programs. The liquidity already exists. Strata surfaces it.

Atomic CPI Execution

When a taker order hits AVL depth, it executes atomically through Sonar CPI swaps. Price guards and slippage protection are enforced inside the instruction itself. If execution deviates from quote, the trade reverts.

A Unified Stack

Manifest and Phoenix expose native resting orders. Jupiter exposes routed swaps. Strata combines native orders, intent liquidity, and external AMM depth in one visible, executable book.

AVL reduces the cold-start problem by surfacing executable external liquidity from the first block, subject to live route availability.

Intent orders: fill or get penalized.

Market makers post intent directly on the order book. Liquidity is supplied just in time at settlement from a balance the maker controls, rather than being locked per order. When a taker hits their level they fill, or their reputation decays. Missed fills are penalized on-chain.

Post Intent. Settle JIT.

A market maker posts a signed offer at a spread directly on-chain. Assets stay in a maker-controlled wallet or vault until settlement. One balance can support quotes across multiple markets at once.

Reputation Penalties

Every missed fill is recorded on-chain, and reputation decays with each one. Persistent non-fillers are deprioritized or removed entirely. Honest market makers rise to the top of the queue.

Capital Efficiency

One maker-controlled balance can support the full quoted range and multiple markets without locking capital at every level. Liquidity is committed just in time when a fill settles.

Professional liquidity without paid market maker programs. Reputation enforces what rebates used to buy.

Built. Working. Trading.

A three-layer CLOB now in public beta on Solana mainnet. Real orders flow, AVL depth is visible on the book, and live pricing is active.

- ✓ Three-layer order book with segmented depth: Real + Intent + AVL
- ✓ Live charting with a real-time Binance WebSocket ticker
- ✓ Merkle root verification with on-chain checkpointing
- ✓ Full order type support: Limit, IOC, FOK, and Post-Only
- ✓ WebSocket feed for depth updates and trade history
- ✓ TypeScript SDK plus a fork-and-go reference market maker bot

One maker position is the depth for every pair.

Correlated baskets, including LSTs, stablecoins, and BTC wrappers, trade in a single shared book. Deposit once, quote everywhere.

28 → 1

8 assets: 28 thin books collapse into one shared pot

~80x

Near-peg depth vs a full-range position at $\pm 1\%$ (the $1/\delta$ law)

\$0

Protocol capital at risk; makers self-custody throughout

No fragmentation

One reserve set and one maker inventory back every pair. Each trade taps the whole pot, not a pre-split 1/28th slice, so every pair gets a better price.

Deep where trades happen

Orbital concentration stacks liquidity in the plus or minus 1% band around parity, where correlated assets actually trade. Same capital, far deeper where it counts.

Rate-aware and rug-proof

LSTs price off the live staking rate and fail closed if it is stale, so no arb leak. Reserves always equal maker balances, so payouts are always fully backed.

Built, audited SHIP, and mainnet public-beta live: a live 5-asset basket cycled every leg on one maker position.

Strata unifies liquidity other venues keep separate.

	STRATA	JUPITER	PHOENIX	OPENBOOK	MANIFEST
Visible order book depth	✓	×	✓	✓	✓
AMM liquidity virtualized on the book	✓	×	×	×	×
Deep on day one, on any pair	✓	×	×	×	×
Native limit orders	✓	×	✓	✓	✓
No paid market maker programs	✓	×	×	×	×
Self-custody throughout	✓	✓	✓	✓	✓
Aggregated route fallback	✓	×	×	×	×

Manifest validates the on-chain CLOB category. Strata's moat is the unified stack: native orders, intent liquidity, and executable external depth.

Idle order collateral can earn while it waits.

THE FLYWHEEL

More yield → More liquidity parked → Deeper books → More volume → More yield

Optional product layer. Candidate Solana money markets are evaluated for audit quality, withdrawal liquidity, oracle risk, and atomic settlement safety.

The book becomes a yield surface. Capital flows where it earns.

Market Makers

Post intent across active pairs and earn spread on fills. Where the optional money-market layer is enabled, eligible idle capital may also earn variable yield. Incentives follow liquidity demand.

Liquidity Providers

Opt into approved Solana money markets while orders rest. Returns are variable and source-specific; collateral remains subject to withdrawal liquidity and protocol risk.

Traders

Trade across native, intent, and aggregated liquidity in one self-custodial venue. AVL broadens execution coverage, subject to user limits and live route availability.

THE SELF-SUSTAINING CYCLE

Liquidity earns → More liquidity arrives → Books deepen → Traders come → Volume grows → Yield increases

Order books are a \$5B to \$15B annual fee market. Solana is the fastest growing slice.

\$1.6T

Solana DEX volume in 2025

\$100T+

Global CLOB volume, CEXs and TradFi

5%

Conservative volume capture target

\$80M+

Annual revenue at a 10 bps average fee

ANNUAL REVENUE BY VOLUME CAPTURE · 10 BPS AVERAGE FEE

THE COMP

Binance spot clears roughly \$15B per day. Hyperliquid perps clear about \$2B per day and command a valuation above \$10B. They proved that professional traders will leave CEXs for on-chain venues with real exchange UX. Manifest and Phoenix validate the on-chain CLOB category. Strata expands it with native orders, intent liquidity, and executable external depth in one book.

12 months. From mainnet beta to full ecosystem.

**NOW**

Public Beta Live

Mainnet public beta with real orders and AVL depth. Professional terminal with TradingView charts.

Shipped: TypeScript SDK plus a fork-and-go reference MM bot.

Q3 2026

Mainnet Expansion

Expand supported markets, harden audits, grow the intent order layer, and onboard the first market maker partners.

Q4 2026

Money Markets

Optional integration with approved Solana money markets, with variable returns, liquidity buffers, and guarded unwind controls.

Q1 2027

Permissionless Pairs

Public pair creation and a token launch program with a 60 percent creator fee revenue share. Long tail activation.

Q2 2027

PvP Layer

On-chain options and prediction markets launch. A full competitive arena where the book becomes a metagame.

We control the spread. The protocol captures the value.

Order Matching MEV

The matcher is the sole crank, and every `settle_trade` batch is sequenced by Strata. The protocol sees the flow first, before anyone else can act on it.

Spread Capture

When a taker order hits AVL depth, the spread between the quoted Sonar price and the executed price flows directly to the protocol vault.

Protocol Vault

All MEV revenue accumulates in the ProtocolVault PDA, on-chain and fully verifiable. This is protocol revenue, not a hidden tax on users.

Built-In, Not Bolted-On

MEV capture is part of the `settle_trade` instruction itself, and the program validates every batch. Strata does not extract MEV. The protocol captures it.

Second Revenue Stream

Trading fees plus MEV capture create two uncorrelated revenue sources from the same order flow. No other Solana DEX has this.

Strata captures the value of its own order flow. No other venue on Solana can do this.

Two builders. One product.

Shipping at 5 to 8x the pace of comparable teams.

Phizen

Product · Strategy · GTM

Drives product direction, market strategy, partnerships, and fundraising. Owns the vision from architecture to go-to-market and leads every investor and market maker conversation.

AL

Engineering · Architecture · Execution

Full-stack engineering across the Rust and Solana programs, the matching engine, the AVL depth sampler, and the front end. Owns the entire technical stack from protocol to pixel.

AI-Augmented Development. We run Overseer, a persistent AI agent that audits every commit, catches regressions, and monitors competitor moves around the clock. Agent-driven development is our force multiplier: two people, 5 to 8x the output.

THE ASK

Raising \$500,000 to build the liquidity layer Solana needs.

\$500,000

RAISE TARGET

● Engineering (2 senior hires)	\$200,000	40%
● Smart contract audits (2 firms)	\$100,000	20%
● Market maker onboarding + BD	\$75,000	15%
● Operating runway	\$75,000	15%
● Infrastructure (RPC, indexers, API)	\$50,000	10%
Total	\$500,000	100%

WHAT WE'RE LOOKING FOR

- ✓ A lead investor with room for strategic angels
- ✓ Solana DeFi advisors for market maker introductions
- ✓ Connections to Wintermute, GSR, and Flowdesk
- ✓ Token launch teams for permissionless pairs
- ✓ CEX relationships for liquidity partnerships
